The **Information Systems Education Journal** (ISEDJ) is a double-blind peer-reviewed academic journal published by **EDSIG**, the Education Special Interest Group of AITP, the Association of Information Technology Professionals (Chicago, Illinois). Publishing frequency is six times per year. The first year of publication is 2003.

ISEDJ is published online (<http://isedj.org>) in connection with ISECON, the Information Systems Education Conference, which is also double-blind peer reviewed. Our sister publication, the Proceedings of ISECON (<http://isecon.org>) features all papers, panels, workshops, and presentations from the conference.

The journal acceptance review process involves a minimum of three double-blind peer reviews, where both the reviewer is not aware of the identities of the authors and the authors are not aware of the identities of the reviewers. The initial reviews happen before the conference. At that point papers are divided into award papers (top 15%), other journal papers (top 30%), unsettled papers, and non-journal papers. The unsettled papers are subjected to a second round of blind peer review to establish whether they will be accepted to the journal or not. Those papers that are deemed of sufficient quality are accepted for publication in the ISEDJ journal. Currently the target acceptance rate for the journal is about 45%.

Information Systems Education Journal is pleased to be listed in the 1st Edition of Cabell's Directory of Publishing Opportunities in Educational Technology and Library Science, in both the electronic and printed editions. Questions should be addressed to the editor at editor@isedj.org or the publisher at publisher@isedj.org.

A combined MIS/DS Course uses Lecture Capture Technology to “Level the Playing Field” in Student Numeracy

Karen Popovich

Abstract

This paper describes the process taken to develop a quantitative-based and Excel™-driven course that combines *BOTH* Management Information Systems (MIS) and Decision Science (DS) modeling outcomes and lays the foundation for upper level quantitative courses such as operations management, finance and strategic management. In addition, course outcomes needed to “level the playing” field for our seemingly growing bi-modal distribution of numeracy skills among business students.

Keywords: course development, online teaching methods, Excel™, management information systems, management/decision science.

1. “I’M IN BUSINESS, BUT I DON’T DO NUMBERS.”

We repeatedly convey to our business students that we live in a complex global environment where the only “known” is change. Our technologically advanced classrooms demonstrate how the Internet allows almost immediate exchange of multifaceted data and information. Through a growing number of pedagogical methods, we consistently strive to improve the effectiveness of our practices as we encourage (and sometimes push) our students to develop a solid background in quantitative methods to support critical analysis and decision making.

Projections are in our favor. The Bureau of Labor Statistics National Employment Matrix indicates employment growth of at least 20% and a median salary of greater than \$60,000 for both computer systems design and management analysts by the year 2018 (Sauter, 2011). A quick search on Monster.com resulted in

hundreds of career possibilities in the college’s regional area.

The beginning pages of the 2007 “College Learning for the New Global Century,” state that graduating college students must possess intellectual and practical skills including:

- Inquiry and analysis
- Critical and creative thinking
- Written and oral communication
- Quantitative and information literacy
- Teamwork and problem solving

The report also summarizes goals for obtaining knowledge of human cultures and the physical and natural world as well as developing personal and social responsibility with a desire for lifelong learning (American Association of Colleges and Universities, 2007).

Discussion in my classes includes the notion of a “business analyst.” Kizior & Hidding (2010) refer to the International Institute of Business Analysis (IIBA) to define the requirements of a

business analyst: a knowledge-worker that understands business problems and opportunities and works as a liaison to analyze, communicate and validate changes to business processes. The chief information officer (CIO) at our college expects a business analyst to have a solid understanding of basic statistics, modeling, Total Quality Management (TQM) tools, process mapping tools and accounting. In addition, expectations include strong written and oral communication skills and an attitude that includes patience, curiosity and listening. Essentially, "one who can translate business needs into technical requirements to effect change in business processes." McClure and Sircar (2008) recommend that innovation and creativity for successful business practices cannot take place without business students learning and applying modeling techniques.

Still, I was *not* surprised to hear the above statement ("...I don't do numbers") uttered one fall day in 2007 in my junior/senior level Production and Operations Management course. Higher education stakeholders have raised concerns over college students' quantitative skills for years (i.e. U.S Department of Education, NCEE, 1983; Murtonen, Olkinuora, Tynjälä & Lettinen, 2008; Arum, A. & Roksa, J. 2010; McClure and Sircar, 2008).

Faculty in the college's Department of Business Administration and Accounting (DBAA) had anecdotally reported for many years that students often arrived in their courses with weak enumerative skills and a low comfort level using quantitative techniques to support decision making. Many of these skills should have been acquired in pre-requisite courses.

Around the same time, it was apparent that our required introductory Management Information Systems (MIS) course was becoming dated as research and experience had shown growing acceptance of online learning technology and general proficiency in Microsoft Office™ (i.e. Davis, Kovacs, Scarpino & Turchek, 2010).

I teach mostly quantitative business courses and am a heavy user of Microsoft Excel™ (in both teaching and research) to support model building, analysis and decision making. With the support of my department chair, I set forth a departmental quest to help our students "do numbers" by developing a quantitative-based and Excel™-driven course that would combine *BOTH* introductory Management Information

Systems (MIS) and Decision Science (DS) modeling outcomes and lay the foundation for upper level quantitative courses, such as Production and Operations Management, Finance and Strategic Management.

From the beginning of the initiative, we recognized that course outcomes needed to "level the playing field" for our noticeable growing bi-modal distribution of numeracy skills among business students. Years of teaching quantitative courses and evidence from numerous student evaluations have shown that the overall learning experience for both students and instructor can be negatively influenced if there is a substantial gap between high-performing students and students that struggle with concepts. Comments in upper level quantitative courses, such as "this is too hard" or "there is too much busy work," necessitated built-in flexibility in the new course structure to address different student skill and comfort levels.

An additional benefit of offering a confluence course so early in the academic career was to emphasize the possibility of students selecting a second major in Computer Science or Information Systems or a minor in Computer Science (McKenzie, 2005). DBAA faculty recognized that Information Systems is a field that involves both technology and people and is constantly changing (Battig, 2010). Given student reluctance to embrace quantitative concepts, focusing on the practical value of computer science or information systems might pique interest in the field.

The following sections describe underlying principles of a new course, identify available campus technology, and review outcome assessment from the course as taught under the 3-credit system. The paper concludes with lessons learned and suggestions for improvement in the college's new curriculum as well as recommendations for future development.

2. RATIONALE FOR AN EXCEL™-BASED QUANTITATIVE COURSE

In late 2007, a curricular initiative addressed the weak numeracy skills evidenced in the college's business (BU) majors. Figure 1 in the appendix displays the course development timeline. Prior to the quest, a mathematics course, either finite mathematics or one of several calculus options,

was a pre-requisite for Business and Accounting majors. DBAA faculty questioned whether students took the “easy way out” and registered for a lower level math, even if the student’s academic record suggested a more advanced course.

A study of five years of entering first-year business students’ high school and college math courses revealed some interesting patterns. Most notably, 50% of the students enrolled in a college math course that was “lower” (that is, covering less sophisticated concepts) than what they completed in high school, with the majority of these students enrolling in college finite mathematics. Topics covered in finite mathematics included matrices, sets, probability, difference equations and game theory.

Discussions with our colleagues in the Department of Mathematics helped us to identify that finite math was no longer meeting the needs of our majors, as determined by upper level course expectations, nor was it increasing their numeracy skills beyond what they had already achieved in high school. It was decided that the DBAA would develop a rigorous course that would construct a foundation for critical skills needed in upper level courses.

A course, *Management Decision-Making Tools* (MDMT) was designed under a two-phase approach. It was first run as a special topics course in Spring 2008 for seniors, with great success and then again in Fall 2009 for first-year students. The rationale for initially teaching seniors was to identify the topics and skill levels that would most benefit first and second year students.

For the second phase, prior to the start of Fall 2009, the Registrar identified a number of incoming declared BU majors who had originally opted for finite mathematics and placed them into the special topics course. An important outcome of that semester was realizing that students would perform better with a statistics pre-requisite. Table 1 in the appendix outlines the original objectives. Renamed *Management Decision Tools* (MDT), the 3-credit course was approved by the college’s Curriculum and Education Policy Committee as an *alternative* to finite mathematics in the Business and Accounting major, effective Fall 2010, with a statistics (either elementary or business) pre-requisite.

With an upcoming Fall 2011 college-wide curriculum transformation, including an overhaul of the liberal arts course requirements, we decided to “wait and see” how the Mathematics department, as well as our Business and Accounting courses, would be revised before establishing MDT as a requirement for the DBAA major. The Mathematics department ultimately terminated finite mathematics and developed a new entry-level college math course available for all college students. The new liberal studies curriculum required a “quantitative reasoning” component. Business and Accounting majors satisfied this requirement by completing a statistics course.

A focal theme of DBAA’s new curriculum was to improve analytical and critical analysis, as our students sometimes opt for a business major because it does not require calculus (although it is *strongly recommended*). Students selecting majors based on perceptions of lower-level quantitative skills as well as the impact after college has been well documented in the literature (i.e. Ganesh, Sun & Barat, 2010; McClure & Sircar, 2008, Holtzman & Kraft, 2010 among others).

The new curriculum, identified college-wide as “4-4,” effectively required all courses to become 4 credit hours and students would take 4 courses each semester, requiring 128 credits for graduation. “4-4” triggered a considerable modification throughout campus as majors had to be limited to 15 total courses, including pre-requisites. The Business major, for example was 18 courses. Our faculty had to re-design courses to meet college and departmental learning goals (see one of five DBAA Learning Goals in the table below). Simultaneously, academic rigor and student engagement across the curriculum intensified with a goal of 10 hours of outside class time work per week per course.

DBAA Learning Goal:

Possess basic competencies necessary to operate and lead in an organizational environment. This includes the areas of group dynamics and operations, financial and quantitative applications and analysis, technology and problem solving.

As mentioned earlier, our *Management Information Systems* course in the existing curriculum was an introductory course often taken in the first or second year. The course introduced students to the role of information technology and information systems in formal organizations. It included the study of the use of information technology to build efficient and effective information systems. A particular focus was on basic development of information systems that provided meaningful information for management decision making. This was accomplished primarily through the Microsoft Office™ suite of applications.

The DBAA faculty, after great debate and meaningful collaboration, decided to combine *Management Information Systems with Management Decision Tools*. Our objective was to integrate faculty and student interaction while linking technology and learning objectives to achieve outcomes. Refer to the exhibit below.

This figure stemmed from the concept of “people, process and technology” which is very popular in the operations management literature for Enterprise Resource Planning (ERP) and Customer Relationship Management (CRM) implementation, see for example, Chen and Popovich, (2003).

In addition to literature on online and hybrid teaching methods for business quantitative courses, I used the “E-Learning Success Model” by Holsapple and Lee-Post (2006) as a framework to develop course projects, that include PowerPoint™ slides, case studies, practice problems, Excel™ tutorials, assignments and assessments. Table 2 in the Appendix provides a listing of grading components used to measure student performance.

3. CLASSROOM TECHNOLOGY

Similar to Davis et al., (2010) this paper used online learning (rather than a myriad of terms such as eLearning, Distance Learning, Technology-Supported Learning, Web-based Learning and computer-based learning) to describe any higher educational course that used technology to deliver all or part of the course content.

Campus-supported technology tools were not new to the campus. eCollege™, (a part of Pearson’ LearningStudio™, similar to Blackboard™ or webCT™) was introduced in 2000 to several graduate classes and piloted to undergraduates during the 2004-05 academic year. Effective Fall 2009, faculty were required by the college to minimally post their syllabi and book list. It should be noted that many faculty members had an extensive eCollege™ site and made use of the many available online learning tools. These tools included online discussion threads, live chat, journaling, webliography, a dropbox for assignments, gradebook, email link and document sharing.

Most classrooms were connected wirelessly and were equipped with an instructor podium, SmartBoard or SmartPodium and an LCD projector as well as connections for laptops, video and document cameras. Faculty members could reserve classroom laptop carts for students that did not have laptops. In Spring 2009, the campus began to experiment with McGraw-Hills lecture-capture software, *Tegrity*™.

Davis et al., (2010), in an exploratory study on IT/IS courses, determined that students preferred “on-ground” (i.e. face-to-face) and “on-ground with online supplement” formats to be more effective in the learning process, with an exception for Microsoft Office™ software. Their study also revealed that students in quantitatively oriented courses would have difficulty in completely online courses. Terry (2007) offers empirical evidence in that online students scored lower in their MBA quantitative course than did students taking the course on campus. Finally, Davis et al., (2010) reported that students preferring online courses were generally non-traditional (in terms of age and work experience) and lived 6-10 miles from campus. Our college is primarily an undergraduate liberal arts institution with 30 majors and 32 minors where nearly all 2,000

students reside on campus. We have a limited offering of hybrid long-distance courses, generally taught during the summer sessions.

My previous experience in quantitative courses at the college confirmed the benefits and struggles of technology use in class. MDT in Spring 2011 was held in a computer lab, equipped with classroom management software and was limited to 25. The class was comprised mostly of first and second year students (with a handful of seniors taking the course as a special elective). The next sections discussed the Spring 2011 MDT 3-credit hour course.

4. COURSE STRUCTURE AND DELIVERY

Classes were held twice a week, on Monday and Wednesday and the instructor offered staggered office hours Monday-Friday, with several Saturday or Sunday afternoons for additional help. Email was responded to quickly (Sebastianelli and Tamimi, 2011) and always within 24 hours. The impact on student outcomes based on personal and electronic interaction between faculty and students, even in large classes, has been documented in the research, most recently by Conn, Boyer, Hu & Wilkinson (2010). Further, the E-Learning Success Model (Holsapple and Lee-Post, 2006) suggested that prompt, responsive, fair, knowledgeable and available faculty were important factors for service quality.

In attempt to capture student interest, as well as to meet the course objectives, while recognizing different learning styles (i.e. Prosperpio & Gioia, 2007), especially given the various quantitative and technological skills of students, cases and projects were integrated into MDT. Baugh (2010) recommended designing a semester project that was relevant to the student. Students in his qualitative study were proud of their results and often exceeded project requirements. Furthermore, students applied technology tools that interested them.

On the first day in Spring 2011, lab policies, which were also posted on the syllabus, emphasized that the computer was for classwork only; otherwise, privileges were revoked. Throughout the semester, there were only a few exceptions to staying focused on classwork and a quick reminder of the class rule solved any issue. Faculty visitors to the class noted that all students were engaged in the Excel™ model and offered assistance to neighboring students.

It was important at the start of the semester, without making students uncomfortable, to identify current knowledge of basic business formulas (such as the profit calculation as well as basic statistical functions, such as mean, median, mode and standard deviation) and Excel™ skill level.

After reviewing the syllabus, a brief non-graded assessment included basic questions involving business calculations and the corresponding Excel™ formulas, functions, charts, formatting and cell references. Students scoring 80% or higher were then identified as Excel™ "geeks" and students scoring below 80% were identified as Excel™ "newbies." The terminology was the class choice and was decided on after several minutes of energetic student interaction.

"Newbies" and "geeks" were then paired (about 8 "geeks" and 17 "newbies") and time was given to allow for introductions and exchange of contact information. Students were not required to sit with their "geek", but they now had access to a peer that would also be able to assist or mentor with course concepts and Excel™. "Geeks" were asked to respond to "newbie" questions within 24 hours. Students commented that they did not often email their "geek" but they knew they had a resource, especially if they missed a day of class. Support for peer mentors in higher education was well researched for retention, academic success and educational experience; see for example, Kram, 1983; Pagan & Edwards-Wilson, 2002; Topping, 1996 and recently Terrion & Leonard, 2010.

The course was split into the following units: overview of MIS, basic Excel™ review (break-even analysis, financial statements, VLOOKUPS, if-statements, Pivot Tables and charting), linear programming (graphically and then solved via Excel's™ Solver and What's Best™ add-in), project management (Gantt Charts, CPM and PERT) regression analysis, forecasting, simulation and decision analysis.

Each unit was one to two weeks in length, dependent on class progress. Students were assigned homework problems: there were "geek" problem sets and "newbie" problem sets. Both problems covered the same material, but the "geek" homework was enhanced with more challenging material. All students had access to all homework problems and "newbies" were

welcome to also attempt “geek” assignments and vice versa.

For example, in a break-even analysis problem, “newbies” would find the break-even point and manually chart the graph of revenues and fixed and variable costs and then respond to questions. “Geeks” had the added challenge of building the chart in Excel™ by solving equations via Goal Seek. A second assignment covered importing web query data from the Bureau of Labor Statistics website (www.bls.gov). Students then created charts in Excel™ to show the trending of various employment fields and salaries. The “geek” portion included Pivot Tables with descriptive statistics of salaries by industry. Interestingly, by the 10th week of the 16 week semester, a little over 80% of the students were working on “geek” problems. By the end of the semester, nearly all students attempted “geek” assignments.

At the completion of each unit, an assessment was delivered. Assessments were two-part: qualitative concepts (written, short-answer or fill-in-the-blank) and a small case study to complete in Excel™ (or by hand graphing, in the case of the introductory linear programming unit).

It did not take long to feel the effects of trying to facilitate 25 students with different learning styles and various proficiency levels without a teaching assistant. Even with the peer mentoring groups, students would become frustrated and/or bored, which could impact class group dynamics (Billson, 1986) and the overall learning environment.

Lecture-capture software, in this case, Tegrity™, provided an interactive solution. Class sessions were pre-recorded (static image of the Instructor downhill skiing, recorded voice and video of step-by-step Excel™ actions) and were available for students via a link from eCollege™. Dey, Burn & Gerdes (2009) suggest that online presentations were helpful for “equation heavy” courses. Sebastianelli and Tamimi (2011) customized audio-video clips that illustrated the use of Minitab and Excel™ in step-by-step screen movements with great success and students found it an essential course component.

Students referred to the MDT class recordings as “mini-me sessions.” One student commented,

The online step-by-step helped me to practice the formulas in Excel™ and were really helpful once I understood the formula by hand. I paused the video and worked through the homework at my own pace.

When asked, students indicated that they did not use the index or searching functions. The lecture-capture software was easy to use, required just a few minutes of training and uploaded to eCollege™ without issue. I spent little time in the editing during the production process– it was not deemed necessary for this course. As with results from the literature (i.e. White, 2009), class attendance did not diminish with the availability of course recordings. It is possible that the students considered this a “small class” and that their absence would be noticed. Attendance was taken daily.

The log results of viewings at the end of the semester showed that 24 of the 25 students viewed all 10 lecture recordings and there were a variety of viewings of homework hints, for a total of 255 viewings. Individual viewings lasted from a few minutes to nearly two hours.

Pre-recorded lectures were not the only resource for demonstrating new topics. Traditional lectures covered each topic thoroughly and step-by-step with demonstration on the LCD projectors during the first 40 to 45 minutes of class. The remaining time, 30 to 35 minutes, was used for students to work in small groups, often with their “geek” on assigned homework problems. One student commented:

There was a lot of work but we were given sufficient time to ask questions in class, either to our mentor or to the professor. I think the combination of teaching methods was effective because of all the example problems she [the professor] walked us through before trying to do the problems on our own. I felt comfortable working outside of class because of the attention the professor was able to give to me during class.

The final project, a semester-based project (Baugh, 2010), was to develop a decision model for “everyday use.” Students were given the opportunity to be creative, to think “outside the box” and transfer their learning into a topic they found interesting. The guidelines included: working in a team of two if desired, use as many

concepts and advanced Excel functions™ as possible and prepare an executive summary that explained the model. Students then presented their models on the last day of the course. The rubric included points for accuracy, complexity, usability, feasibility and formatting. A few examples are described in Table 3 in the appendix.

5. LESSONS LEARNED

The six seniors in the course, in addition to their course evaluations, were asked to consider how this course could be taught under the new curriculum. Each student wrote a two-to-four page reflection that offered some positive insights as well as constructive feedback on their experience. The information in this section is based upon my notes, student evaluations, faculty visitor comments and the senior reflections. Main concepts garnered identified that online tools, such as lecture-capture, improved the learning environment for both students and instructor; assessment tools were well received and the seniors also made suggestions to institute a personal portfolio and class-based journal.

At the beginning of the semester, before the implementation of the lecture-capture software, the experience could be summarized in one word: exhausting. Even though the instructor had already incorporated eCollege™ for the syllabus, daily agendas, helpful links, handouts and grading, it really was the online lecture-capture software that turned the course from a potential failure. Prosperio & Goia (2007) suggest that teachers were responsible for circumventing disconnects between current teaching methods and the technology rich “virtual generation” learning methods.

The “production” of the audio recordings and the step-by-step video procedure did take time. However, it was an effective preparation tool for class. Once the process was practiced several times it was actually very easy; even though the decision models were increasing in complexity. The pre-recorded sessions allowed the instructor to focus on the students during class time and cover more examples and application of models:

I felt that during this class I was learning valuable information about Excel™ however at times I felt like it was a little tough to keep up to pace. With the videos in front of me it was not so hard

to keep up with how Excel™ worked and more class time was spent being able to understand WHY Excel™ worked.

The videos allowed us to focus more on class time to ask questions and learn from those answers and to work with other people.

Because we had the online videos, I feel as though a worthwhile assignment could be adding a mini project at the end of each topic on top of the assessment so we could apply these models to a business scenario.

Students generally viewed assessments as a better evaluative tool than exams; although, in a sense, they were essentially one in the same. The main difference, though, was that the assessments were unit based rather than time based throughout the semester. Only one unit was assessed at a time. Several students felt that for concepts such as linear programming, simulation and forecasting, they needed more time to absorb the material. With the change from three to four credits, it will be possible to spend more time on each topical area. Surprisingly, students recommended quizzes. Students felt that quizzes would ensure that everyone was caught up on the chapter and supplemental reading material.

An interesting mention was made for both online discussion threads and building project portfolios. The discussion thread would:

offer the students and you [instructor] the ability to share thoughts and opinions on subjects in class. For example, the section on simulation models. Many businesses employ these types of models into their operations. Through discussion threads each person could find a real life situation where simulations are used. You [instructor] could also ask more in-depth questions that we would be able to have an even better understanding of the models we learned. I believe this would be key to understanding new material and retaining the information.

Samkin & Francis (2008) suggest that, for those students who engage with them, learning portfolios could contribute by facilitating a deep

approach to learning. The authors applied both a learning portfolio and personal journal entries to a third year accounting course.

A student recommended a semester portfolio as beneficial for reference in other courses. "We could even be "hired out" as consultants to the Introduction to Business course as they develop their business plans." One student stated, "I've been asked by my friends to help with Excel™ for their Finance course. It was fun to teach them something new." Another commented that "I have learned how useful and important Excel™ could be and it is just as important to know how to do the decision models and be able to teach someone else how to use modeling."

Students appreciated the chance to create their own decision model at the end of the semester, as shown by the comments above. Many students felt that each unit should have a small decision model that would "help a real company and we could have informal presentations a few times during the semester. This would also help us improve our presentation skills and show how many possibilities there were to use these models."

Beginning with Spring 2012 registration, it will be important to assess whether students pursue further courses in computer science or information systems. Furthermore, how students apply these concepts to their upper level business courses must be evaluated.

6. CONSIDERATIONS

As in any teaching method, there were a number of issues to be considered.

1. Faculty must be prepared to integrate technology into the classroom and must be willing to improve their technical skills. For example, faculty have been known to resist the latest version of Microsoft Office™ with the "ribbon toolbar." Adding to the complexity is learning to use Excel™ in both PC and MAC formats.
2. Murtonen (2008) suggested that students who experienced problems with learning quantitative methods did not necessarily have problems with learning mathematics, but their views and beliefs from previous experiences might not support the learning process. In my classes, I hear "I don't like math." If we can modify the negative connotation associated with quantitative methods and link theory to practice, such as MDT is designed, our student's performance might indicate better transfer of knowledge and improved overall learning.
3. The relatively small class size, due to lab seating limitations, was actually helpful in many ways. There were a variety of skill sets within the class and it would have been difficult to give each person equal assistance if the class was much larger than 25. A limited class size is often a recommendation in courses involving online elements. The inclusion of peer mentors was also helpful; although their work was often checked to make sure it was correct. Students were able to get to know one another more in this class by helping each other resulting in a close sense of a learning community.
4. Business students were quite used to a combination of online and "traditional" teaching methods. They were very comfortable accessing information from eCollege™ and downloading videos to their laptops or mp3 players. What was new was the ability to learn quantitative models using Excel™. In addition to learning the decision model under study, they had to develop their own skill set. Another recommendation by a student was to keep a journal that worked as an Excel™ "how-to" guide.
5. Zhu (2010) suggested that in a virtual classroom community, students demonstrated active participation, especially when experiences linked academic and social settings together. Several students recommended the importance of online discussion groups and one student stated, "keeping a journal and seeing what other students were doing would be useful to help me reproduce concepts to other classes."
6. Dey *et al.*, (2009) in their exploratory research found significant differences in transferring concepts between live lecture and multimedia and video presentation. Students watching the multimedia presentation scored higher than their counterparts that just listened to the lecture. It will be valuable to study whether other DBAA faculty feel that students quantitative and Excel™ skills improve over time. It will not be for several semesters before these students will be "tested" on their retention.

DBAA faculty presume that students will be prepared for upper level course work. Miller & Brooks (2010) suggest a deviation of SERVQUAL (Parasuraman, Zeithaml, & Berry, 1988) called ClassQual to evaluate overall "service" quality in the education setting, especially in regards to course content, faculty concern and student satisfaction.

7. How will the students "carry" learned concepts to other classes? Additional research on retention and confidence in numeracy skills needs to be studied as students take advanced quantitative courses. Rustagi (1997) examines retention of quantitative methods between courses and results are not overly positive. A difficulty with the MDT course is that it is placed early in the student's academic career. It is possible that an entire year could go by before a higher level business quantitative course is taken. The DBAA plans on studying the impact of this course as students continue in their academic program.

7. CONCLUSION

Millennial students are inundated with technology bells and whistles that encourage multi-tasking on a habitual basis: texting, updating Facebook and Twitter statuses, listening to music via their iPod or Pandora, occasionally taking a phone call, checking (several) email accounts and possibly writing a term paper, using online resources. Embraced, the virtual environment could actually create different opportunities for learning (Prosperio & Gioia, 2007).

Dey *et al.*, (2009) remind us that the digital generation would demand more interactive instruction. As faculty, we develop curricula based on our practices, attitudes, beliefs and technology skill sets. At the college, our faculty benefit from the strong resources of an effective team in Instructional Technology Services. In the end, our students ability "to do numbers" and apply information system concepts may well depend on the efficient integration of student and faculty interaction in a virtual world.

Figure 1: Management Decision Tools (MDT) Course Development Timeline

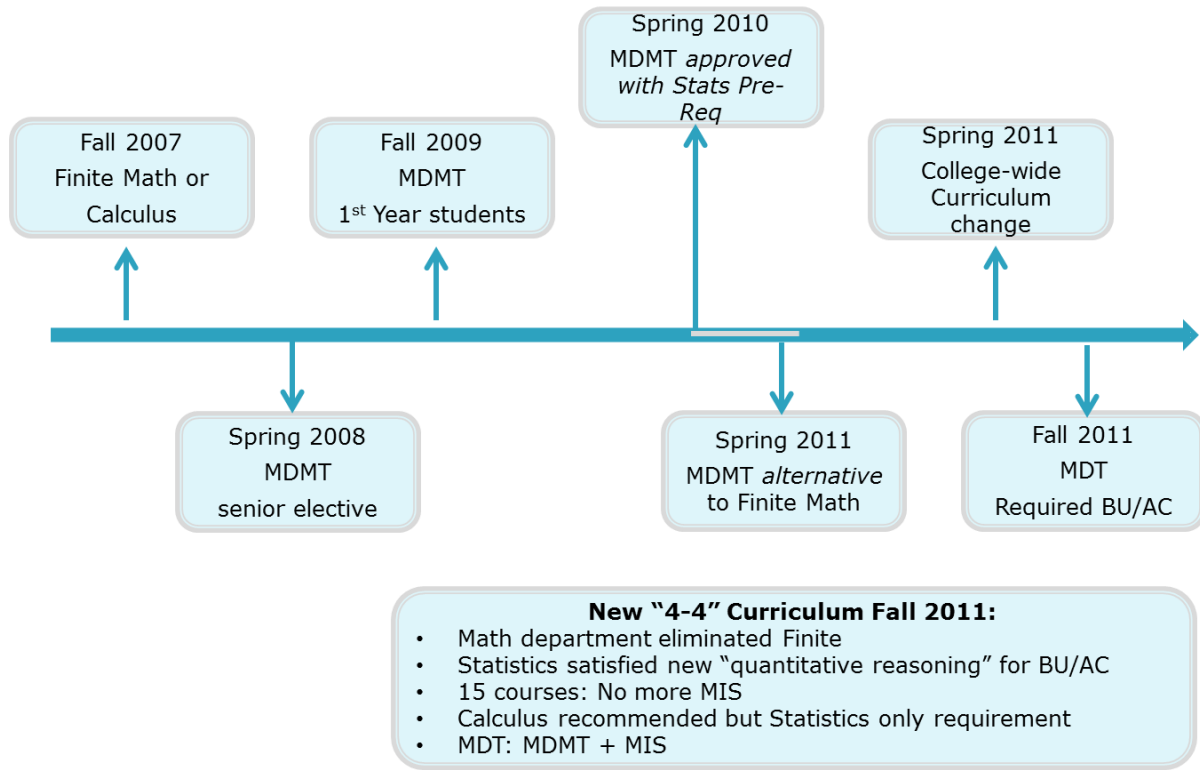

Table 1: Management Decision-Making Tools Special Topics (original) Course Description:**Course Description:**

This course provides an introduction to the concepts and methods of Management (also known as Decision) Science, which involves the application of mathematical modeling and analysis to management problems. It also provides a foundation in modeling with spreadsheets. The primary goals of the course are to help you develop logic to build business models and analyze diverse decision-making scenarios utilizing computer software. Another important goal is to encourage a disciplined process to approach management situations.

More specifically, the course will:

- Introduce you to the basic principles and techniques of applied mathematical modeling for managerial decision-making. These methods will be applied to problems arising in a variety of functional areas of business, including economics, accounting, finance, marketing and operations. Sample topics include linear & nonlinear programming, project management, simulation, decision analysis, forecasting and queuing.
- Show you how to use Excel™ spreadsheets effectively for business analysis. You will learn a comprehensive set of spreadsheet skills and tools, including how to design, build, test and implement a spreadsheet.
- Sharpen your ability to structure problems and to perform logical analyses. You will practice translating descriptions of business situations into formal models and you will investigate those models in an organized fashion.
- Expose you to settings in which models can be used effectively. You will apply modeling concepts in practical situations. You will learn to extract insight from models and to use those insights to communicate, persuade and motivate change.

Textbook: *Managerial Decision Modeling with Spreadsheets*, by Balakrishnan, Render & Stair. 2nd Edition

**Table 2: Management Decision Tools (MDT)
Grading Components/Student Assessment in the New Curriculum**

Description:	Points
Linear Programming Assessment	100
Project Management Assessment	100
Decision Analysis Assessment	100
Simulation Assessment	100
Forecasting Assessment	100
Homework	100
Journal	100
Excel™ in the "Real World"	75
Custom Decision Model	75
Why IT projects fail paper	50
Quizzes	50
Project Presentations	50
Total	1000*

Table 3. Final Project Descriptions

<i>Project Title</i>	<i>Description</i>
Take me to the ballpark	Two students designed a network flow diagram for a trip to Boston for a Red Sox game, including rest areas, eating options, parking and overnight accommodations. To apply the critical path concept, they used a random number generator to apply "happiness" scores. The critical path determined the "happiest" way through the network. As the random numbers would re-calculate, the critical path would adjust and with the use of conditional formatting, would "light up" in Red Sox colors.
Stats, Stats and More Stats	A varsity baseball player collected statistics from the college's division competitors. Using a series of regression analyses, pivot tables and charting, he was able to provide a working model of key players as well as find statistically significant results on batting averages.
Scarves, anyone?	A two student team developed a business model, including forecasting and simulation, to determine net profit for their first year business course which required a business plan.
Is it Tax Season?	An accounting student developed a simulation model that would identify the profit of his tax preparation service for international firms. Firms with higher revenues were charged a higher preparation fee. The model included complex if-statements, VLOOKUPS and charting.
Leaving on a Jet Plane	A student from New York City developed a linear programming model that analyzed the optimal way home for various school vacations: bus, train, or plane. Constraints included an overall budget, travel times and a minimum number of flights needed to receive the maximum possible frequent flier points. There was also a constraint for "parental demand" for trips. The model was easily adapted to several other students in class.
